EUCALYPT

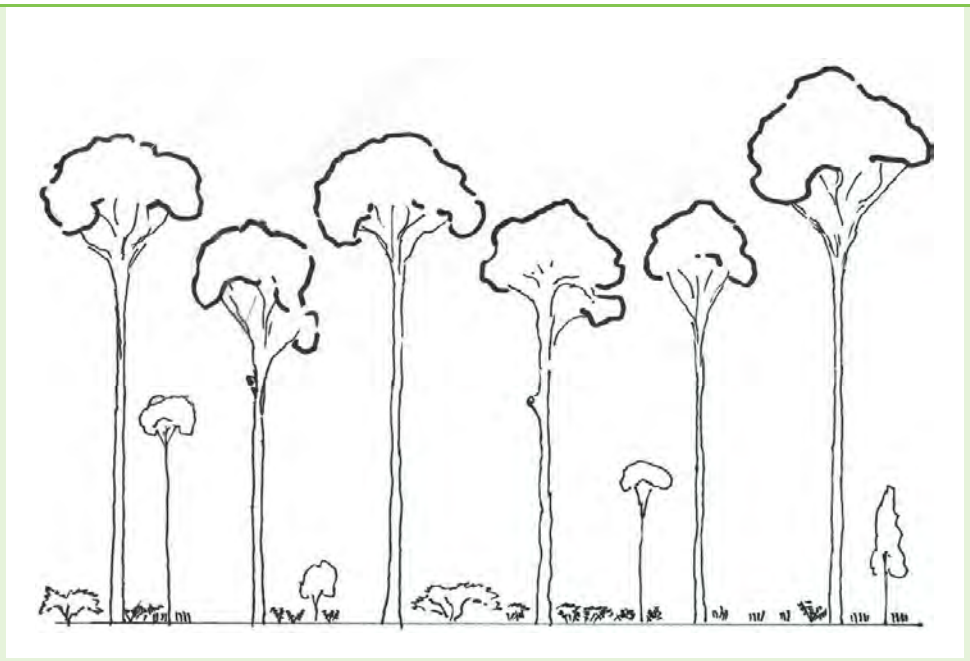
VEGETATION TYPE 1a

Regional Ecosystem: 12.11.3

White Mahogany +/- Tallowwood - Grey Gum (*Eucalyptus acmenoides* +/- *E. microcorys* - *E. propinqua*) Open Forest on Metasediments

COMMUNITY STRUCTURE

Vegetation type (VT) 1a is typically a tall open forest adjoining rainforest. It has a relatively dense canopy (60-65% cover*). The canopy layer is typically 19-32m high, with White Mahogany (*Eucalyptus acmenoides*) often dominant, with *E. microcorys*, *E. propinqua* and *E siderophloia* also often present.



Source: Searle, 2019 (derived from Ryan *et al*, 2019; GC33; GC57)

The sub-canopy is sparse and mainly composed of Brush Box (*Lophostemon confertus*) and eucalypt saplings. The shrub layer is sparse yet diverse in some locations. The ground layer is dominated by grasses and/or ferns (particularly *Entolasia stricta*, *Cymbopogon refractus, Imperata cylindrica*, *Doodia aspera* and *Blechnum cartilagineum*), with a diverse array of sub-shrubs (including *Solanum stelligerum* and *Zieria collina*) also present. Vines are uncommon. Where fire is excluded, ferns, cycads and other rainforest plants like gingers become more prolific

Characteristic plant species

Approximately **84 native plants** species have been recorded for this vegetation type. Characteristic plant species for this vegetation type are listed below. Dominant (most numerous) species are shaded.

Indicates species is a preferred koala food tree*

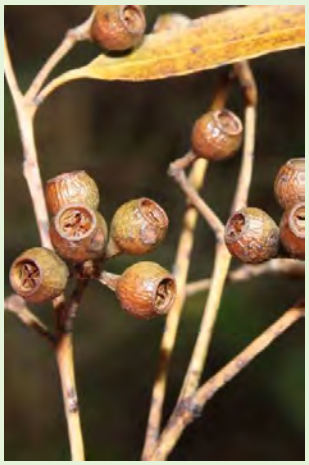
GBC Indicates species is a Glossy Black-Cockatoo feed tree species

CWS Indicates species is a City-wide significant species

* It is noted that in addition to preferred food trees, koalas utilise a range of eucalypt and non-eucalypt tree species for supplemental feeding and other uses such as shelter. These other species are also important and necessary features of koala habitat.

CANOPY

Upper layer of vegetation exposed to sunlight which creates a canopy that shades lower layers



White Mahogany
Eucalyptus acmenoides

Tallowwood
Eucalyptus microcorys

Small-fruited Grey Gum
Eucalyptus propinqua

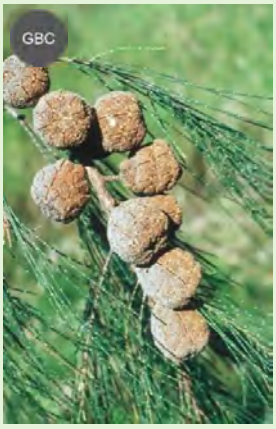
Grey Ironbark
Eucalyptus siderophloia

Pink Bloodwood
Corymbia intermedia

Brush Box
Lophostemon confertus

SUB-CANOPY

Tree layer below canopy



Forest She-Oak
Allocasuarina torulosa

Brush Box
Lophostemon confertus

Hickory Wattle
Acacia disparrima subsp. disparrima

SHRUB LAYER

Middle layer of vegetation usually made up of small trees (including juvenile canopy and sub canopy tree species) and woody shrubs

Hickory Wattle
Acacia disparrima subsp. disparrima

Devils Needles
Solanum stelligerum

Mt Tamborine Ziera *Zieria collina*

Golden Pea
Daviesia arborea

Waddy Wood *Trochocarpa laurina*

GROUND LAYER AND VINES

Lowest layer of vegetation. Plant types can include grasses; graminoids (non-woody plants with a grass-like morphology); ferns; and forbs (non-woody, broad-leaved, flowering plants). Grasses constitute most of the ground cover although ferns are prominent in some cases. Vines are uncommon.

Gristle Fern
Blechnum cartilagineum

FERN

Kangaroo Grass
Themeda triandra

TUSSOCK GRASS

Blady Grass
Imperata cylindrica

GRASS

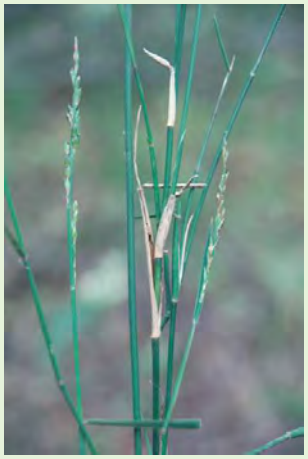
Bluegrass
Poa cheelii

GRASS



Wiry Panic
Entolasia stricta

TUSSOCK GRASS

Barbwire Grass
Cymbopogon refractus

GRASS

Prickly Rasp Fern
Doodia aspera

FERN

City-wide significant plant species

The City of Gold Coast recognises species which are locally significant as City-wide significant (CWS) species. These species are important because they may be threatened, restricted to the Gold Coast, or at the edge of their geographic range. In addition to characteristic species identified above as CWS species, the following CWS plant species may also be present in this vegetation type.

Ironbark Orchid
Dendrobium aemulum
EPIPHYTE

Rainforest Carex
Carex breviculmis
GRASS

Palm Lily
Cordyline congesta
PALM

Shirley's Nightshade
Solanum shirleyanum
SHRUB

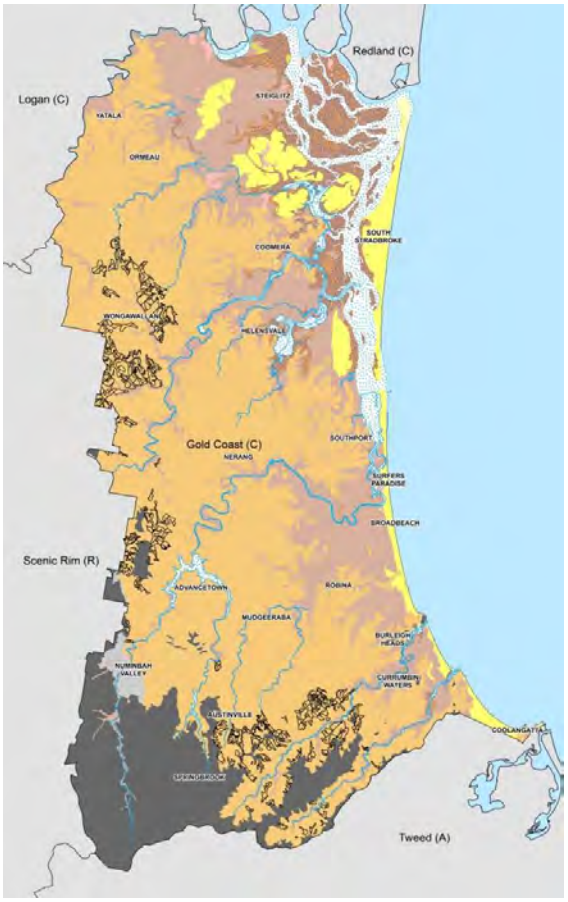
Tongue Orchid
Dockrillia linguiformis
EPIPHYTE

OCCURRENCE

Native plants occur in vegetation communities, which are consistently associated with a particular soil type, landform (shape of the land, e.g. hills or plains) aspect (position on a slope in relation to the sun) and climate.

This vegetation type occurs on higher hillslopes and escarpment areas on deep fertile soils, typically with deep leaf litter, high organic and good moisture content. This community is largely restricted to the Wongawallan and Mt Tamborine areas in the central western parts of Gold Coast City, often adjoining rainforest.

Historic distribution of Vegetation Type 1a



LEGEND

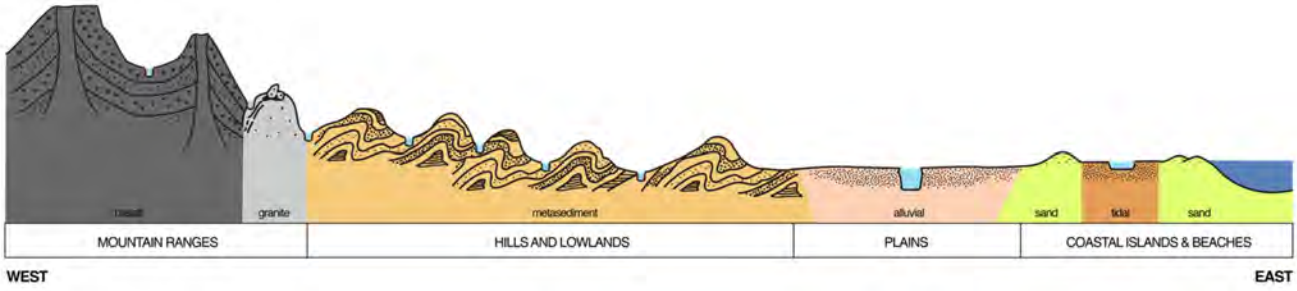
Vegetation Type 1a | Ocean | Major Waterways

COMMON LANDFORMS AND GEOLOGY OF THE GOLD COAST

	LAND FORM	GEOLOGY (soils and rocks)	AGE
	Tidal flats and beaches (subject to tidal inundation)	Water logged, saline muds, clays and sands	Youngest
	Coastal dunes (not subject to tidal inundation)	Sand	
	Flood plains, river and creek flats	Alluvial soils (soils moved or shaped by water)	
	Level or gently undulating plains	Sandy or loamy soils	
	Mountain ranges, hills, lowlands and coastal headlands	Basalt (volcanic) rocks	
	Undulating	Sedimentary rocks	
	Mountain ranges, hills and lowlands	**Metasediment rocks***	
	Mountain ranges, hills, lowlands and coastal headlands	Granite (volcanic) rocks	Oldest

Conceptual cross section of Gold Coast

Showing typical location of most common geology and land forms (concept only, not to scale)



*** Metasediment rocks**

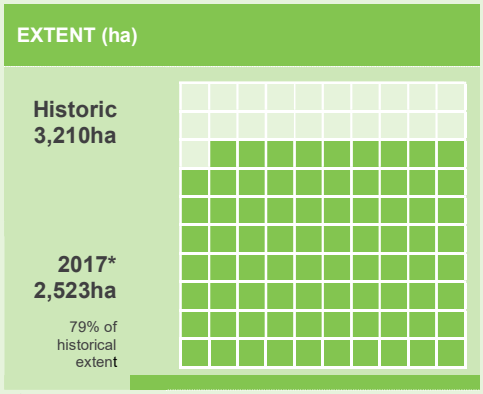
The most common underlying geology on the Gold Coast is metasediment rocks. Metasediment rocks are a type of metamorphic rock (rock transformed by heat and pressure). Originally these rocks were sedimentary rocks which were formed on the ocean floor through the deposition and solidification of sediment. These sedimentary rocks were subsequently buried underneath other rocks and subjected to high pressures and temperatures, causing the rock to recrystallize. This recrystallization process is known as metamorphosis, hence the term metamorphic rocks. About 300 million years ago these metamorphic rocks were pushed upward by geologic processes, creating much of the ranges, hills and lowlands on the Gold Coast.

2017 EXTENT AND CONSERVATION STATUS

Gold Coast

The 2017 extent* of this vegetation type on the Gold Coast is 2,524 hectares

1 HECTARE (HA) = 2.46 ACRES = THE SIZE OF AN INTERNATIONAL RUGBY FIELD



* Extent as mapped in 2017. Includes remnant vegetation only. Does not include disturbed remnant or regrowth

Queensland

The conservation status of vegetation in Queensland is specified under the Vegetation Management Act 1999, which lists this regional ecosystem (RE 12.11.3) as being of 'Least Concern'.

LIKELIHOOD OF BECOMING EXTINCT (in QLD) due to biodiversity loss/degradation

THREATS

This vegetation type is largely restricted to more fertile escarpment areas adjoining rainforest and is susceptible to infestation by Lantana and other dense understorey growth, particularly in the absence of fire. It is a naturally restricted vegetation type that can transition towards rainforest in the absence of fire, and relies on appropriate fire management (low frequency, moderate to high intensity fires). Weed and fire management are key to the healthy management of this vegetation type. Please refer to the Queensland Government's Regional Ecosystem Description Database for more information including suggested fire regimes.

Common threats to all vegetation types

Clearing
Native vegetation is protected by Federal, State and local legislation. However, with increasing population growth in the region, Southeast Queensland is experiencing large amounts of vegetation clearing, particularly in areas designated for urban development. Protecting native vegetation on your property is one of the most beneficial things you can do to protect wildlife and the natural environment.

Weeds
Environmental weeds are the second biggest threat to our natural environment after land clearing. Environmental weeds (introduced plants that have naturalised and are invading our bushland) degrade our natural environment by:

- out competing native plant species for available nutrients and light,
- taking over and transforming native landscapes often leading to local plant or animal extinctions and loss of biodiversity,
- reducing the availability of food and other resources for many native animals whilst sometimes benefiting pest animals,
- increasing the risk of destructive wildfire,
- often being toxic to people and animals.

Fire
Very broadly, vegetation types are either adapted to fire or fire sensitive. Fire can become a threat if:

- it extends into vegetation types which should not be burnt e.g. rainforest,
- the frequency and/or intensity of the fire is too high,
- the area burnt is too large.

Grazing
The grazing of animals like cattle, horses, goats and feral animals such as deer can cause trampling or loss of diversity of seedlings and compact soil, preventing natural regeneration.

Collecting
Unethical and illegal collection of plant specimens in the wild poses a serious threat to some species, particularly orchids, grass trees and epiphytes.

Climate change
Changes in temperature and rainfall can have significant effects on our city's vegetation. For example, without consistent rainfall, areas become drier, potentially resulting in higher fire frequency and/or intensity, which some plants and vegetation communities won't be able to tolerate. Plants (and animals) need available space to migrate as conditions change, with high altitude species at the greatest risk as there is nowhere suitable for them to go. Warmer conditions may also provide the right habitat for a greater variety of weeds. As sea levels rise, salt water moves further upstream and vegetation also becomes inundated.
